Data Information

Ge the data from: http://www.nyc.gov/html/tlc/html/about/trip_record_data.shtml (2016 data) The data used in the attached datasets were collected and provided to the NYC Taxi and Limousine Commission (TLC)

Information on taxis:

Yellow Taxi: Yellow Medallion Taxicabs

These are the famous NYC yellow taxis that provide transportation exclusively through street-hails. The number of taxicabs is limited by a finite number of medallions issued by the TLC. You access this mode of transportation by standing in the street and hailing an available taxi with your hand. The pickups are not pre-arranged.

For Hire Vehicles (FHVs)

FHV transportation is accessed by a pre-arrangement with a dispatcher or limo company. These FHVs are not permitted to pick up passengers via street hails, as those rides are not considered pre-arranged.

Green Taxi: Street Hail Livery (SHL)

The SHL program will allow livery vehicle owners to license and outfit their vehicles with green borough taxi branding, meters, credit card machines, and ultimately the right to accept street hails in addition to pre-arranged rides.

Credits: Quora

Footnote:

In the given notebook we are considering only the yellow taxis for the time period between Jan - Mar 2015 & Jan - Mar 2016

Data Collection

We Have collected all yellow taxi trips data from jan-2015 to dec-2016(Will be using only 2015 data)

```

Features in the dataset:

Field Name	Description
VendorID	A code indicating the TPEP provider that provided the record. Creative Mobile Technologies VeriFone Inc.
tpep_pickup_datetime	The date and time when the meter was engaged.
tpep_dropoff_datetime	The date and time when the meter was disengaged.
Passenger_count	The number of passengers in the vehicle. This is a driver-entered value.
Trip_distance	The elapsed trip distance in miles reported by the taximeter.
Pickup_longitude	Longitude where the meter was engaged.
Pickup_latitude	Latitude where the meter was engaged.
RateCodeID	The final rate code in effect at the end of the trip. Standard rate JFK Newark Nassau or Westchester Negotiated fare Group ride
Store_and_fwd_flag	This flag indicates whether the trip record was held in vehicle memory before sending to the vendor, aka "store and forward," because the vehicle did not have a connection to the server. Y= store and forward trip N= not a store and forward trip
Dropoff_longitude	Longitude where the meter was disengaged.
Dropoff_latitude	Latitude where the meter was disengaged.
Payment_type	A numeric code signifying how the passenger paid for the trip. Credit card Cash Cash No charge Dispute Lunknown Code signifying how the passenger paid for the trip. Credit card Cash No charge Lunknown Code signifying how the passenger paid for the trip. Credit card Cash No charge Code signifying how the passenger paid for the trip. Credit card Cash No charge Code signifying how the passenger paid for the trip. Credit card Cash No charge Code signifying how the passenger paid for the trip. Credit card Cash No charge
Fare_amount	The time-and-distance fare calculated by the meter.
Extra	Miscellaneous extras and surcharges. Currently, this only includes. the $0.50 and 1$ rush hour and overnight charges.
MTA_tax	0.50 MTA tax that is automatically triggered based on the metered rate in use.
Improvement_surcharge	0.30 improvement surcharge assessed trips at the flag drop. the improvement surcharge began being levied in 2015.
Tip_amount	Tip amount – This field is automatically populated for credit card tips. Cash tips are not included.
Tolls_amount	Total amount of all tolls paid in trip.
Total_amount	The total amount charged to passengers. Does not include cash tips.

ML Problem Formulation

Time-series forecasting and Regression

- To find number of pickups, given location cordinates(latitude and longitude) and time, in the query reigion and surrounding regions.

To solve the above we would be using data collected in Jan - Mar 2015 to predict the pickups in Jan - Mar 2016.

Performance metrics

- 1. Mean Absolute percentage error.
- 2. Mean Squared error.

Data Cleaning

In this section we will be doing univariate analysis and removing outlier/illegitimate values which may be caused due to some error

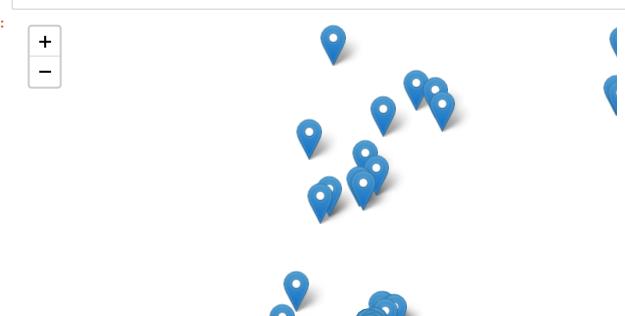

[n [5]:	<pre>#table below shows few datapoints along with all our features month.head(5)</pre>

1. Pickup Latitude and Pickup Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115) that New York is bounded by the location cordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with pickups which originate within New York.

```
In [6]: # Plotting pickup cordinates which are outside the bounding box of New-York
        # we will collect all the points outside the bounding box of newyork city to o
        utlier locations
        outlier locations = month[((month.pickup longitude <= -74.15) | (month.pickup
        latitude <= 40.5774) | \
                            (month.pickup longitude >= -73.7004) | (month.pickup latitu
        de >= 40.9176))
        # creating a map with the a base location
        # read more about the folium here: http://folium.readthedocs.io/en/latest/quic
        kstart.html
        # note: you dont need to remember any of these, you dont need indeepth knowled
        ge on these maps and plots
        map_osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
        # we will spot only first 100 outliers on the map, plotting all the outliers w
        ill take more time
        sample locations = outlier locations.head(10000)
        for i,j in sample locations.iterrows():
            if int(j['pickup_latitude']) != 0:
                folium.Marker(list((j['pickup latitude'],j['pickup longitude']))).add
        to(map_osm)
        map_osm
```

Out[6]:

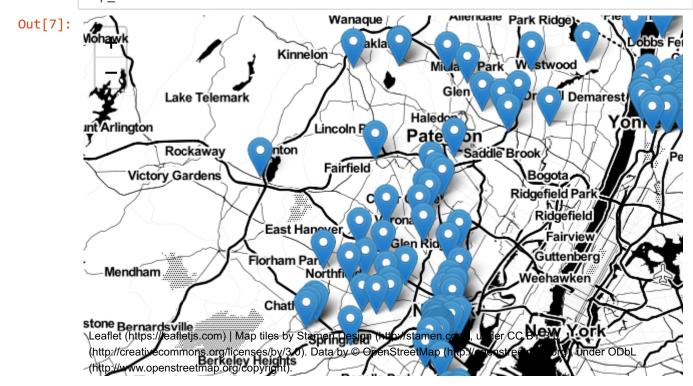

Leaflet (https://leafletjs.com) | Map tiles by Stamen Design (http://stamen.com), under CC BY 3.0 (http://creativecommons.org/licenses/by/3.0). Data by © OpenStreetMap (nttp://openstreetmap.org), under ODbL (http://www.openstreetmap.org/copyright).

Observation:- As you can see above that there are some points just outside the boundary but there are a few that are in either South america, Mexico or Canada

2. Dropoff Latitude & Dropoff Longitude

It is inferred from the source https://www.flickr.com/places/info/2459115) that New York is bounded by the location cordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any cordinates not within these cordinates are not considered by us as we are only concerned with dropoffs which are within New York.

```
In [7]: # Plotting dropoff cordinates which are outside the bounding box of New-York
        # we will collect all the points outside the bounding box of newyork city to o
        utlier_locations
        outlier locations = month[((month.dropoff longitude <= -74.15) | (month.dropof
        f latitude <= 40.5774) \
                            (month.dropoff longitude >= -73.7004) | (month.dropoff lati
        tude >= 40.9176))]
        # creating a map with the a base location
        # read more about the folium here: http://folium.readthedocs.io/en/latest/quic
        kstart.html
        # note: you dont need to remember any of these, you dont need indeepth knowled
        ge on these maps and plots
        map osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
        # we will spot only first 100 outliers on the map, plotting all the outliers w
        ill take more time
        sample locations = outlier locations.head(10000)
        for i, j in sample locations.iterrows():
            if int(j['pickup_latitude']) != 0:
                folium.Marker(list((j['dropoff latitude'],j['dropoff longitude']))).ad
        d to(map osm)
        map_osm
```

Observation:- The observations here are similar to those obtained while analysing pickup latitude and longitude

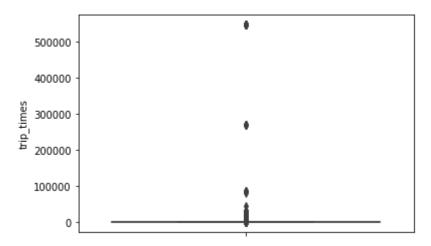

3. Trip Durations:

According to NYC Taxi & Limousine Commision Regulations the maximum allowed trip duration in a 24 hour interval is 12 hours.

```
In [8]: #The timestamps are converted to unix so as to get duration(trip-time) & speed
        also pickup-times in unix are used while binning
        # in out data we have time in the formate "YYYY-MM-DD HH:MM:SS" we convert thi
        ss sting to python time formate and then into unix time stamp
        # https://stackoverflow.com/a/27914405
        def convert to unix(s):
            return time.mktime(datetime.datetime.strptime(s, "%Y-%m-%d %H:%M:%S").time
        tuple())
        # we return a data frame which contains the columns
        # 1.'passenger_count' : self explanatory
        # 2. 'trip distance' : self explanatory
        # 3.'pickup_longitude' : self explanatory
        # 4.'pickup latitude' : self explanatory
        # 5. 'dropoff_longitude' : self explanatory
        # 6.'dropoff_latitude' : self explanatory
        # 7. 'total amount' : total fair that was paid
        # 8. 'trip times' : duration of each trip
        # 9.'pickup_times : pickup time converted into unix time
        # 10. 'Speed' : velocity of each trip
        def return with trip times(month):
            duration = month[['tpep_pickup_datetime','tpep_dropoff_datetime']].compute
        ()
            #pickups and dropoffs to unix time
            duration_pickup = [convert_to_unix(x) for x in duration['tpep_pickup_datet
        ime'].values]
            duration drop = [convert to unix(x) for x in duration['tpep dropoff dateti
        me'].values]
            #calculate duration of trips
            durations = (np.array(duration drop) - np.array(duration pickup))/float(60
        )

```

Observation:- As even the 99.9th percentile value doesnt look like an outlier,as there is not much difference between the 99.8th percentile and 99.9th percentile, we move on to do graphical analysis

```
In [34]: #below plot shows us the fare values(sorted) to find a sharp increase to remov
    e those values as outliers
    # plot the fare amount excluding last two values in sorted data
    plt.plot(var[:-2])
    plt.show()
```

```
In [35]: # a very sharp increase in fare values can be seen
# plotting last three total fare values, and we can observe there is share inc
rease in the values
plt.plot(var[-3:])
plt.show()
```

Remove all outliers/erronous points.

Inference:

• The main objective was to find a optimal min. distance(Which roughly estimates to the radius of a cluster) between the clusters which we got was 40

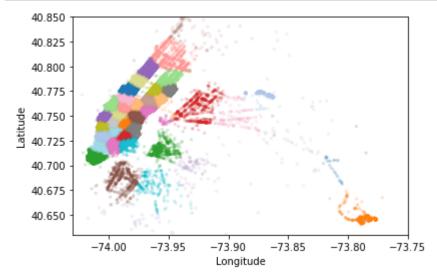

```
In [40]: # if check for the 50 clusters you can observe that there are two clusters wit
h only 0.3 miles apart from each other
# so we choose 40 clusters for solve the further problem

# Getting 40 clusters using the kmeans
kmeans = MiniBatchKMeans(n_clusters=40, batch_size=10000,random_state=0).fit(c
oords)
frame_with_durations_outliers_removed['pickup_cluster'] = kmeans.predict(frame
_with_durations_outliers_removed[['pickup_latitude', 'pickup_longitude']])
```

```

In [56]: # why we choose, these methods and which method is used for which data?

Ans: consider we have data of some month in 2015 jan 1st, 10 _ _ _ 20, i.e t here are 10 pickups that are happened in 1st

10st 10min intravel, 0 pickups happened in 2nd 10mins intravel, 0 pickups happened in 3rd 10min intravel

and 20 pickups happened in 4th 10min intravel.

in fill_missing method we replace these values like 10, 0, 0, 20

where as in smoothing method we replace these values as 6,6,6,6,6, if you can check the number of pickups

that are happened in the first 40min are same in both cases, but if you can observe that we looking at the future values

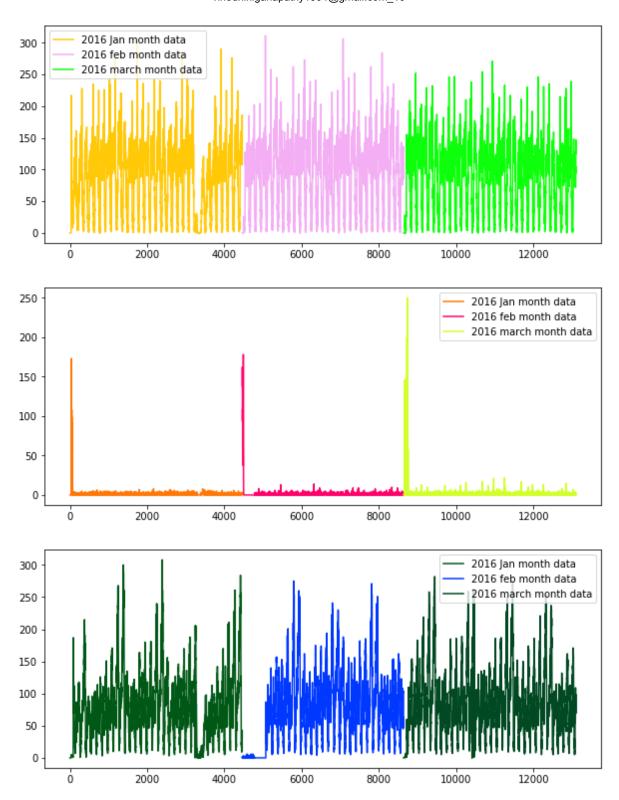

wheen you are using smoothing we are looking at the future number of pickups which might cause a data leakage.

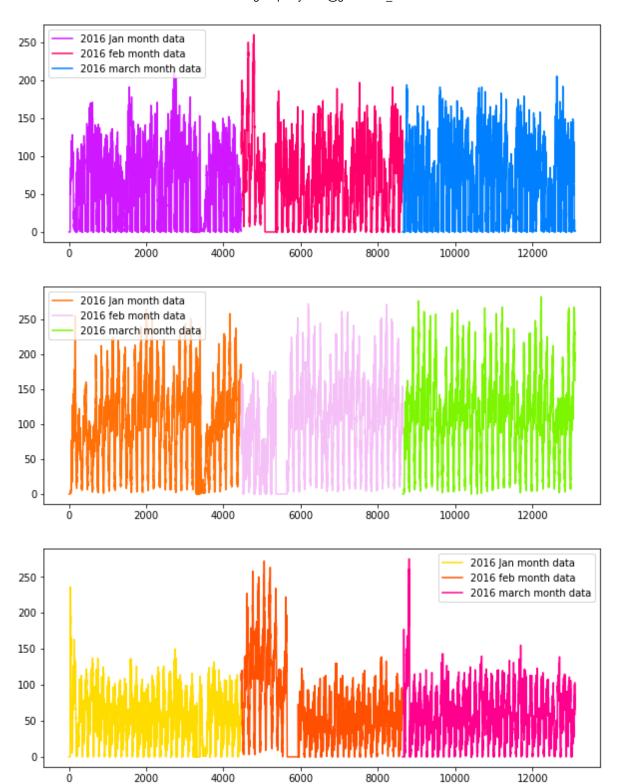

so we use smoothing for jan 2015th data since it acts as our training data # and we use simple fill misssing method for 2016th data.

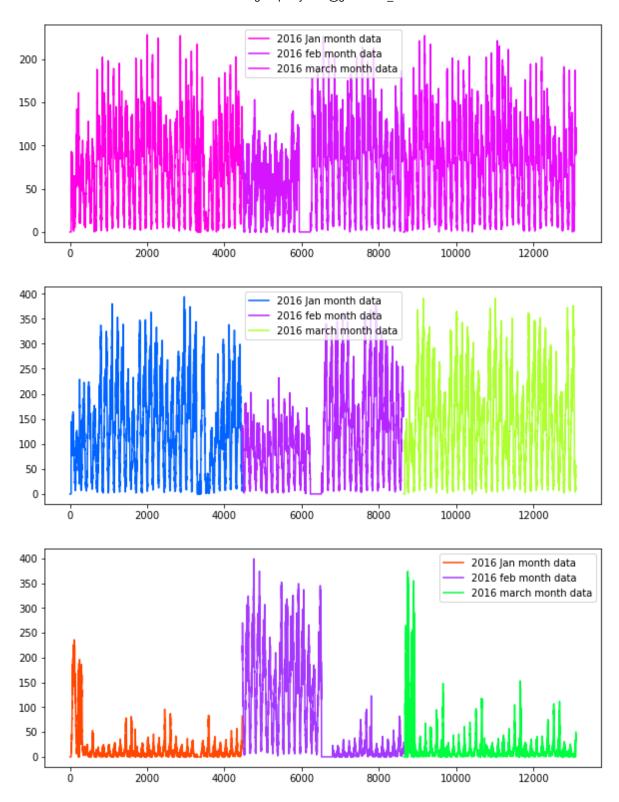

```

Modelling: Baseline Models

Now we get into modelling in order to forecast the pickup densities for the months of Jan, Feb and March of 2016 for which we are using multiple models with two variations

- 1. Using Ratios of the 2016 data to the 2015 data i.e $\,R_t = P_t^{2016}/P_t^{2015}$
- 2. Using Previous known values of the 2016 data itself to predict the future values

Simple Moving Averages

The First Model used is the Moving Averages Model which uses the previous n values in order to predict the next value

Using Ratio Values - $R_t = (R_{t-1} + R_{t-2} + R_{t-3} \dots R_{t-n})/n$

```
In [61]: def MA R Predictions(ratios, month):
             predicted ratio=(ratios['Ratios'].values)[0]
             error=[]
             predicted values=[]
             window size=3
             predicted ratio values=[]
             for i in range(0,4464*40):
                  if i%4464==0:
                      predicted_ratio_values.append(0)
                      predicted values.append(0)
                      error.append(0)
                      continue
                  predicted ratio values.append(predicted ratio)
                  predicted values.append(int(((ratios['Given'].values)[i])*predicted ra
         tio))
                 error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted
          ratio)-(ratios['Prediction'].values)[i],1))))
                  if i+1>=window size:
                      predicted ratio=sum((ratios['Ratios'].values)[(i+1)-window size:(i
         +1)])/window size
                 else:
                      predicted ratio=sum((ratios['Ratios'].values)[0:(i+1)])/(i+1)
             ratios['MA_R_Predicted'] = predicted values
             ratios['MA R Error'] = error
             mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(r
         atios['Prediction'].values))
             mse_err = sum([e**2 for e in error])/len(error)
             return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 3 is optimal for getting the best results using Moving Averages using previous Ratio values therefore we get $R_t = (R_{t-1} + R_{t-2} + R_{t-3})/3$

Next we use the Moving averages of the 2016 values itself to predict the future value using

$$P_t = (P_{t-1} + P_{t-2} + P_{t-3} \dots P_{t-n})/n$$

```
In [62]: def MA P Predictions(ratios, month):
             predicted value=(ratios['Prediction'].values)[0]
             error=[]
             predicted_values=[]
             window size=1
             predicted ratio values=[]
             for i in range(0,4464*40):
                  predicted values.append(predicted value)
                 error.append(abs((math.pow(predicted value-(ratios['Prediction'].value
         s)[i],1))))
                 if i+1>=window size:
                      predicted value=int(sum((ratios['Prediction'].values)[(i+1)-window
         _size:(i+1)])/window_size)
                 else:
                      predicted value=int(sum((ratios['Prediction'].values)[0:(i+1)])/(i
         +1))
             ratios['MA P Predicted'] = predicted values
             ratios['MA P Error'] = error
             mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(r
         atios['Prediction'].values))
             mse_err = sum([e**2 for e in error])/len(error)
             return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 1 is optimal for getting the best results using Moving Averages using previous 2016 values therefore we get $P_t=P_{t-1}$

Weighted Moving Averages

The Moving Avergaes Model used gave equal importance to all the values in the window used, but we know intuitively that the future is more likely to be similar to the latest values and less similar to the older values. Weighted Averages converts this analogy into a mathematical relationship giving the highest weight while computing the averages to the latest previous value and decreasing weights to the subsequent older ones

Weighted Moving Averages using Ratio Values -

$$R_t = (N*R_{t-1} + (N-1)*R_{t-2} + (N-2)*R_{t-3}....1*R_{t-n})/(N*(N+1)/2)$$

```
def WA R Predictions(ratios, month):
    predicted ratio=(ratios['Ratios'].values)[0]
    alpha=0.5
    error=[]
    predicted values=[]
    window_size=5
    predicted ratio values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted_ratio_values.append(0)
            predicted values.append(0)
            error.append(0)
            continue
        predicted ratio values.append(predicted ratio)
        predicted values.append(int(((ratios['Given'].values)[i])*predicted ra
tio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted
ratio)-(ratios['Prediction'].values)[i],1))))
        if i+1>=window size:
            sum values=0
            sum of coeff=0
            for j in range(window_size,0,-1):
                sum values += j*(ratios['Ratios'].values)[i-window size+j]
                sum of coeff+=j
            predicted ratio=sum values/sum of coeff
        else:
            sum values=0
            sum of coeff=0
            for j in range(i+1,0,-1):
                sum values += j*(ratios['Ratios'].values)[j-1]
                sum of coeff+=j
            predicted ratio=sum_values/sum_of_coeff
    ratios['WA_R_Predicted'] = predicted_values
    ratios['WA_R_Error'] = error
    mape err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(r
atios['Prediction'].values))
    mse err = sum([e**2 for e in error])/len(error)
    return ratios, mape err, mse err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 5 is optimal for getting the best results using Weighted Moving Averages using previous Ratio values therefore we get $R_t = (5*R_{t-1} + 4*R_{t-2} + 3*R_{t-3} + 2*R_{t-4} + R_{t-5})/15$

Weighted Moving Averages using Previous 2016 Values -

$$P_t = (N*P_{t-1} + (N-1)*P_{t-2} + (N-2)*P_{t-3}....1*P_{t-n})/(N*(N+1)/2)$$

```
def WA P Predictions(ratios, month):
    predicted value=(ratios['Prediction'].values)[0]
    error=[]
    predicted values=[]
    window size=2
    for i in range(0,4464*40):
        predicted values.append(predicted value)
        error.append(abs((math.pow(predicted value-(ratios['Prediction'].value
s)[i],1))))
        if i+1>=window_size:
            sum values=0
            sum_of_coeff=0
            for j in range(window_size,0,-1):
                sum values += j*(ratios['Prediction'].values)[i-window size+j]
                sum of coeff+=j
            predicted_value=int(sum_values/sum_of_coeff)
        else:
            sum values=0
            sum of coeff=0
            for j in range(i+1,0,-1):
                sum_values += j*(ratios['Prediction'].values)[j-1]
                sum of coeff+=j
            predicted_value=int(sum_values/sum_of_coeff)
    ratios['WA P Predicted'] = predicted values
    ratios['WA P Error'] = error
    mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(r
atios['Prediction'].values))
    mse err = sum([e**2 for e in error])/len(error)
    return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 2 is optimal for getting the best results using Weighted Moving Averages using previous 2016 values therefore we get $P_t=(2*P_{t-1}+P_{t-2})/3$

Exponential Weighted Moving Averages

https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average (https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average) Through weighted averaged we have satisfied the analogy of giving higher weights to the latest value and decreasing weights to the subsequent ones but we still do not know which is the correct weighting scheme as there are infinetly many possibilities in which we can assign weights in a non-increasing order and tune the hyperparameter window-size. To simplify this process we use Exponential Moving Averages which is a more logical way towards assigning weights and at the same time also using an optimal window-size.

In exponential moving averages we use a single hyperparameter alpha (α) which is a value between 0 & 1 and based on the value of the hyperparameter alpha the weights and the window sizes are configured. For eg. If $\alpha=0.9$ then the number of days on which the value of the current iteration is based is~ $1/(1-\alpha)=10$ i.e. we consider values 10 days prior before we predict the value for the current iteration. Also the weights are assigned using 2/(N+1)=0.18, where N = number of prior values being considered, hence from this it is implied that the first or latest value is assigned a weight of 0.18 which keeps exponentially decreasing for the subsequent values.

```
R'_{t} = \alpha * R_{t-1} + (1 - \alpha) * R'_{t-1}
```

```

```

Comparison between baseline models

We have chosen our error metric for comparison between models as MAPE (Mean Absolute Percentage Error) so that we can know that on an average how good is our model with predictions and MSE (Mean Squared Error) is also used so that we have a clearer understanding as to how well our forecasting model performs with outliers so that we make sure that there is not much of a error margin between our prediction and the actual value

```

Regression Models

Train-Test Split

Before we start predictions using the tree based regression models we take 3 months of 2016 pickup data and split it such that for every region we have 70% data in train and 30% in test, ordered date-wise for every region

```
In [73]: # Preparing data to be split into train and test, The below prepares data in c
         umulative form which will be later split into test and train
         # number of 10min indices for jan 2015= 24*31*60/10 = 4464
         # number of 10min indices for jan 2016 = 24*31*60/10 = 4464
         # number of 10min indices for feb 2016 = 24*29*60/10 = 4176
         # number of 10min indices for march 2016 = 24*31*60/10 = 4464
         # regions cum: it will contain 40 lists, each list will contain 4464+4176+4464
         values which represents the number of pickups
         # that are happened for three months in 2016 data
         # print(len(regions cum))
         # 40
         # print(len(regions cum[0]))
         # 12960
         # we take number of pickups that are happened in last 5 10min intravels
         number of time stamps = 5

```

Conclusion:

- 1. Fourier features has been implemented and a slight improvement in MAPE was been observed.
- 2. Great reduction in MAPE (<12%) was influenced by the introduction of triple exponential smoothing.
- 3. RandomForest and XGBoost models are considered to be the best ones as they are neither overfit nor has high MAPE.
- 4. Linear Regression model generated low MAPE after the data was standardized while RandomForest and XGBoost based models didn't require any standardization.

Assignments
